20 Abstract

21 The privacy paradox states that people's concerns about online privacy are unrelated to

22 their online sharing of personal information. Using a representative sample of the German

23 population, which includes 1403 respondents who were interviewed at three waves

separated by 6 months, we investigate the privacy paradox from a longitudinal perspective.

We differentiate between-person relations from within-person effects. Results of a

26 cross-lagged panel model with random intercepts revealed that people who were more

27 concerned about their online privacy than others also shared slightly less personal

28 information online and had substantially more negative attitudes toward information

sharing (between-person level). People who were more concerned than usual also shared

30 slightly less information than usual (within-person level). We found no long-term effects of

privacy concerns on information sharing or attitudes 6 months later. The results provide

further evidence against the privacy paradox, but more research is needed to better

understand the variables' potential causal relation.

A Longitudinal Analysis of the Privacy Paradox

38 Introduction

37

The privacy paradox states that the information disclosure of Internet users is 39 problematic: Although many people are concerned about their online privacy, they still 40 share plenty of personal information on the web (e.g., Acquisti & Grossklags, 2003). The privacy paradox and its underlying theoretical conundrum is hence of considerable interest to society—it is discussed in newspapers (Frean, 2017), Wikipedia entries (Wikipedia, 2018), designated websites (New York Public Radio, 2018), books (Trepte & Reinecke, 2011), and top-tier academic journals (Acquisti, Brandimarte, & Loewenstein, 2015). If the privacy paradox really exists, it should inspire worry: It would suggest that online behavior is irrational and that people are revealing too much of their personal lives to unknown third parties, which can cause various problems (e.g., Sevignani, 2016). Understanding why people disclose information online and whether or not this is paradoxical therefore 49 represents an important challenge. 50 However, current research on the privacy paradox has one major limitation: To the 51 best of our knowledge, most empirical studies conducted so far have investigated the 52 privacy paradox from a between-person (i.e., interpersonal) perspective. By employing 53 empirical tests of relations between people (e.g., cross-sectional questionnaires analyzed with multiple regression or Pearson correlations), studies have analyzed whether people who are more concerned than others also share less personal information than others. Although such a between-person perspective is interesting and represents a viable first step, it cannot make informed claims regarding causality. The privacy paradox, however, implies a causal perspective: Does a person, if he or she becomes more concerned about online privacy, then also share less personal information? This mismatch is problematic because although between-person relations are, except for some special cases, a necessary condition for causal within-person effects, they are by no means a sufficient one. For example, it could be that the between-person relation is determined other third variables.

Hence, as the next step in investigating the privacy paradox and to better understand the causal relation between privacy concerns and information sharing, it is necessary to 65 conduct studies with within-person designs. 66

With this study we aim to answer four major questions. First, on a between-person 67 level, how are concerns about online privacy related to the online sharing of personal information? Second, on a within-person level, does information sharing decrease when 69 concerns increase? Third, what are the potential long-term effects, are changes in concerns related to changes in information sharing 6 months later and/or vice versa? Fourth, what 71 is the role of privacy attitudes, do they mediate the relation between privacy concerns and information sharing? To best answer and contextualize these questions, we first provide an in-depth theoretical analysis of the privacy paradox, after which we present the empirical results of a longitudinal panel study.

A Brief History of the Privacy Paradox

89

Acquisti and Grossklags (2003) were among the first to argue that the online 77 disclosure of personal information is paradoxical. "Experiments reveal that very few 78 individuals actually take any action to protect their personal information, even when doing so involves limited costs" (p.1). Three years later, Barnes (2006) discussed the behavior of young people on SNSs, popularizing the term privacy paradox. Barnes listed six aspects of online behavior that she considered to be particularly paradoxical: (a) illusion of privacy, (b) high quantity of information sharing, (c) attitude behavior discrepancy, (d) lack of privacy concerns, (e) lack of privacy literacy, and (f) fabrication of false information. Norberg, Horne, and Horne (2007) were one of the first to empirically analyze the privacy 85 paradox explicitly. The study found a mismatch between concerns and behavior, which is aligned with several other experimental studies conducted at the time (Beresford, Kübler, & Preibusch, 2012; Hann, Hui, Lee, & Png, 2007; Huberman, Adar, & Fine, 2005). 88 While there are various understandings and operationalizations of the privacy

paradox (Kokolakis, 2017), subsequent research focused on Barnes's third tenet, the attitude-behavior discrepancy. Whereas some studies reported that privacy concerns were 91 not significantly related to the disclosure of personal information (e.g., Gross & Acquisti, 92 2005; Taddicken, 2014; Tufekci, 2008), which lends credence to the privacy paradox, a 93 different set of studies showed significant relations (e.g., Dienlin & Trepte, 2015; Heirman, Walrave, & Ponnet, 2013; Walrave, Vanwesenbeeck, & Heirman, 2012), which refutes the 95 privacy paradox. 96 Notably, in a parallel line of research other studies have also analyzed the relation 97 between privacy concerns and information sharing. However, the term privacy paradox was 98 often not mentioned explicitly. Instead, studies have referred to the so-called privacy 99 calculus, which states that sharing personal information is affected by both the respective 100 costs and the anticipated benefits (Culnan & Armstrong, 1999). By now, several studies 101 have found empirical support for the privacy calculus in various online contexts (e.g., Bol et 102 al., 2018; Dienlin & Metzger, 2016; Krasnova, Spiekermann, Koroleva, & Hildebrand, 2010). 103 Baruh, Secinti, and Cemalcilar (2017) published the first empirical meta-analysis on 104 the relations between privacy concerns and various forms of social media use (e.g., 105 information sharing or SNS usage). On the basis of 37 studies, Baruh et al. (2017) found a 106 small and significant statistical relation between concerns about online privacy and online 107 information sharing (r = -.13, 95% CI [-.07, -.18]). Another more recent meta analysis by 108 Yu, Li, He, Wang, and Jiao (2020) also finds a significant bivariate relation between 109 privacy concerns and information sharing, albeit smaller (r = -.06, 95% CI [-.01, -.12]). 110 There also exist several systematic literature reviews on the privacy paradox (Barth & 111 Jong, 2017; Gerber, Gerber, & Volkamer, 2018; Kokolakis, 2017). Kokolakis (2017) come to 112 the conclusion that "the dichotomy between privacy attitude and behaviour should not be 113 considered a paradox anymore." (p. 130) However, the authors also note that the privacy 114 paradox is a "complex phenomenon that has not been fully explained yet". Barth and Jong 115 (2017) are more skeptical, and argue that "attempts to theoretically explain and practically 116

solve the problem of the privacy paradox are still scarce and we feel the subject deserves far more research attention" (p. 1052).

119 Defining Privacy Concerns and Information Sharing

Privacy is defined as the "[...] voluntary and temporary withdrawal of a person from 120 the general society through physical or psychological means [...]" (Westin, 1967, p. 7). 121 Hence, privacy captures aspects of both volitional control and social separateness. Several 122 dimensions of privacy have been proposed. For example, it is possible to distinguish a 123 vertical and a horizontal level. Whereas the vertical level captures privacy from authorities, 124 institutions, or companies, horizontal privacy addresses privacy from peers, colleagues, or 125 other people (Masur, 2018). When it comes to concerns in general, interestingly they do 126 not seem to be established as a stand-alone theoretical concept in psychology (Colman, 127 2015). Lexically, concerns are defined as a "marked interest or regard usually arising 128 through a personal tie or relationship" that also reflect an "uneasy state of blended 129 interest, uncertainty, and apprehension" (Merriam-Webster, 2018). Concerns therefore 130 represent both a latent motivation (or increased attention), a negatively valenced emotion 131 (or affective condition), and are mostly implicit. As a theoretical construct, privacy 132 concerns can hence be categorized as an affective motivational disposition. As such, there 133 are many similarities with other concepts, including emotions (e.g., fear, anxiety), moods 134 (e.g., dismay, fatigue), attitudes (risk perception, approval), values (e.g., autonomy, 135 freedom), personality traits (e.g., introversion, risk avoidance), and even physiological 136 activation (e.g., attention, arousal). Taken together, concerns about online privacy 137 represent how much an individual is motivated to focus on his or her control over a 138 voluntary withdrawal from other people or societal institutions on the Internet, 139 accompanied by an uneasy feeling that his or her privacy might be threatened. 140 The online sharing of personal information, on the other hand, captures how much 141 person-related information people share when they use the Internet, including information 142

about their age, sex, name, address, health, and finances. Information sharing can be
differentiated from communication and self-disclosure. Communication is broad, because it
comprises all verbal and nonverbal information that is emitted (e.g., Watzlawick, Bavelas,
Jackson, & O'Hanlon, 2011). Self-disclosure is narrow, because it focuses on deliberate
revelations about the true self to others (e.g., Jourard, 1964). Information sharing is even
more specific, because it addresses only person-related information but ignores other types
of self-disclosure such as personal fears, values, or plans.

150 The Relation Between Privacy Concerns and Information Sharing

Currently, there is a lack of studies that explicitly analyze how behavior is affected by

concerns in general. Fortunately, however, we know much about the behavioral effects of

related concepts such as attitudes or fears, which all can affect behavior profoundly

(Fishbein & Ajzen, 2010; Rogers, 1983). Emotions, perhaps the concept most closely

related to concerns, have a particularly strong effect on behavior. By causing fight, flight,

or freeze reactions, they are a primordial trigger of behavior and are considered to be an

adaptive mechanism of evolved species (Dolan, 2002).

Also empirically, concerns have been shown to affect behavior. People more concerned about the environment show more environment-related behaviors (Bamberg, 2003). People more concerned about their appearance consume fewer calories (Hayes & Ross, 1987). People more concerned about their bodies engage in more physical exercise (Reel et al., 2007). Taken together, it is reasonable to expect that also concerns about online privacy should reflect in the online sharing of personal information.

At the same time, there are some factors that are likely to diminish the relation.

Most prominently, there is the so-called *attitude behavior gap* (Fishbein & Ajzen, 2010),

which states that people sometimes act against their own attitudes. Not everyone

concerned about his or her physical health exercises regularly. The explanation is simple:

Other factors such as subjective norms and perceived behavioral control also determine

behavior (Ajzen, 1985), which automatically reduces the impact of attitudes or concerns. 169 Specifically, two of the most influential factors that affect online information sharing are 170 (a) strong subjective norms (Heirman et al., 2013) and (b) expected benefits (Krasnova et 171 al., 2010). In other words, users often prioritize social support, special offers, or improved 172 services. Trepte, Dienlin, and Reinecke (2014) listed several factors that can additionally 173 attenuate the relation: lack of strength of concerns, absence of negative personal 174 experiences, or situational constraints due to social desirability. In conclusion, also in the 175 context of the privacy paradox we should not expect to find a perfect relation between 176 attitudes and behaviors. Expecting a small to moderate relation is more reasonable. 177

Finally, there are also some methodological explanations why some studies did not 178 detect statistically significant relations. Researchers are always confronted with the 179 so-called *Duhem-Quine problem*, which holds that it is impossible to test theories in isolation, because empirical tests always rely on auxiliary assumptions (Dienes, 2008). In 181 other words, if a psychological experiment fails, we do not know whether the theory is 182 wrong or the questionnaire subpar. This tenet is particularly relevant for the privacy 183 paradox: Detecting statistical significance for small effects—and in this case, we should 184 expect to find small effects—is more challenging because it means that large samples are 185 necessary to guarantee sufficient statistical power. Precisely, in order to be capable of 186 detecting a correlation between privacy concerns and information sharing in 95% of all 187 cases, which Baruh et al. (2017) estimated to be r = -.13, we need a sample of N = 762188 people. The reality, however, looks different: In their meta-analysis, Baruh et al. (2017) 189 reported a median sample size of N=300, which can explain why several studies did not 190 find significant effects. 191

In conclusion, in line with prior research and the within-person rationales presented above, we expect to find a small significant relation between privacy concerns and

192

¹ Statistical power describes the probability of statistically detecting an effect that exists empirically. Only with high statistical power is it possible to make valid claims about an effect's existence (Cohen, 1992).

information sharing, both on the between-person level and the within-person level.

Hypothesis 1: People who are more concerned about their online privacy than others will also be less likely to share personal information online than others.

Hypothesis 2: People who are more concerned about their online privacy than they usually are will also share less personal information online than they usually do.

Although short-term effects are likely, it is still unclear whether long-term effects

199 Long-Term Perspective

200

exist as well. First, when analyzing potential long-term effects, it is important to choose an 201 interval that is both plausible and relevant. (It makes a large difference whether the effects 202 of alcohol consumption on driving performance are tested after 1 minute, 1 hour, or 1 day.) 203 One factor that determines an interval's optimal length is the stability of the variables 204 (Dormann & Griffin, 2015). Privacy concerns and privacy attitudes are predominantly 205 trait-like constructs with high stabilities, which is why they necessitate longer intervals. 206 Other studies with comparable research questions have used an interval of 6 months (e.g., 207 Valkenburg & Peter, 2009), which we consider to be plausible also in this case. 208 In general, we believe that it should be possible to find long-term effects. It has been 209 argued that privacy concerns affect privacy behavior in the long run (e.g., Heirman et al., 210 2013). The underlying theoretical mechanism could be that the emotional part of privacy 211 concerns causes (a) motivated information selection and (b) motivated information 212 processing, which is likely to change actual behavior (Nabi, 1999). Specifically, when 213 privacy concerns increase (e.g., because of experienced or witnessed privacy infringements), 214 people might begin reading more media articles on privacy issues and might also consume 215 these articles more carefully, which could prompt information sharing practices that are 216 more cautious. Also empirically, a study with 290 participants found small negative 217 longitudinal (between-person) relations between privacy concerns and self-disclosure 218 (Koohikamali, French, & Kim, 2019). 219

At the same time, the adverse effect of information sharing on privacy concerns seems 220 plausible as well, with two potential outcomes. On the one hand, the long-term relation 221 could be negative: If people start to share more information online, they might become 222 increasingly aware that their privacy is at risk, thereby stirring concern. On the other 223 hand, the long-term relation might also be positive: When people share more personal 224 information online they might become accustomed to doing so, which potentially reduces 225 concern (for example, due to the mere exposure effect; Zajonc, 1968). Finally, there could 226 also be no long-term relation at all: People might have already become used to sharing 227 information online, which stifles further cognitive or emotional processing. This rationale is 228 central to so-called privacy cynicism (e.g., Hoffmann, Lutz, & Ranzini, 2016). 229 Research Question 1.1: Do changes in concerns about online privacy affect the online 230 sharing of personal information 6 months later? Research Question 1.2: Do changes in the online sharing of personal information 232

The Role of Attitudes

233

245

affect concerns about online privacy 6 months later?

It has been argued that privacy attitudes could bridge the gap between concerns and 235 information sharing (e.g., Dienlin & Trepte, 2015). In contrast to privacy concerns, privacy 236 attitudes capture a more explicit, fluctuating cognitive appraisal. Although both variables 237 are related to information disclosure, attitudes are likely the better predictor. This 238 reasoning follows the rational choice paradigm (Simon, 1955), which maintains that 239 behavior is always at least partially influenced by convictions, attitudes, and cost-benefit 240 analyses. Also empirically, a study of 1,042 youths from Belgium found that the relation 241 between privacy attitudes and disclosure of personal information was strong (r = .56), 242 whereas the relation between privacy concerns and disclosure was only moderate (r = -.29; 243 Heirman et al., 2013). 244

Hypothesis 3.1: People who are more concerned about their online privacy than

others will also hold a less positive attitude toward the online sharing of personal information than others.

Hypothesis 3.2: People with a more positive attitude toward the online sharing of personal information than others will also share more information online than others.

Hypothesis 4.1: People who are more concerned about their online privacy than they usually are will also hold a less positive attitude toward the online sharing of personal information than they usually do.

Hypothesis 4.2: People with a more positive attitude toward the online sharing of personal information than they usually have will also share more information online than they usually do.

Concerning the potential long-term relations of privacy attitudes, we are confronted
with the same situation mentioned above. Because we are not aware of research on
long-term relations, several scenarios seem plausible. Attitudes could either have long-term
relations or not, and information sharing could either foster privacy attitudes or diminish
them.

Research Question 2.1: Do changes in concerns about online privacy affect attitudes toward the online sharing of personal information 6 months later?

Research Question 2.2: Do changes in attitudes toward the online sharing of personal information affect concerns about online privacy 6 months later?

Research Question 3.1: Do changes in attitudes toward the online sharing of personal information affect the online sharing of personal information 6 months later?

Research Question 3.2: Do changes in the online sharing of personal information affect attitudes toward the online sharing of personal information 6 months later?

269 Method

Statistics

We follow the recommendation by Daniel Lakens et al. (2018) and first justify the 271 choice of our alpha level. We determined adequate error margins by considering the 272 potential implications of both false positive and false negative findings (i.e., alpha and beta 273 errors): On the one hand, if we committed an alpha error, we would wrongfully conclude that people's concerns and behaviors are consistent. Communicating such a false result to the public might unjustly reassure people when they should be more alert. On the other 276 hand, if we committed a beta error, we would wrongfully conclude that individuals behave 277 paradoxically. Communicating such a false result would unjustly accuse people of 278 implausible behavior, potentially causing unnecessary distress or reactance. We consider 279 both errors to be equally detrimental. Hence, we chose balanced error rates, setting a 280 maximum error rate of 5% for both alpha and beta. As the smallest effect size of interest 281 (SESOI; Daniël Lakens et al., 2018), we chose to consider effects that are at least small 282 (i.e., standardized coefficients above $\beta = .10$; Cohen, 1992) as able to offer empirical 283 support for our theoretical hypotheses; significantly smaller effects were not considered able 284 to offer support. The six hypotheses were tested with a one-tailed approach and the six 285 research questions with a two-tailed approach. On the basis of the balanced alpha-beta 286 approach with a maximum error probability of 5%, a desired power of 95%, and an SESOI 287 of $\beta = 0.10$, we calculated a minimum sample size of 1,293 respondents. Given the final 288 sample size of 1,403 respondents (see below), alpha and beta errors were balanced for our 289 hypotheses (research questions) when we used a critical alpha of 3% (4.20%), resulting in a 290 power of 97% (95.80%) to detect small effects. 291 The data were analyzed using of a random-intercept cross-lagged panel model 292 (RI-CLPM) (Hamaker, Kuiper, & Grasman, 2015). For a visualization, see Figure 1. Note 293 that in contrast to regular cross-lagged panel models (CLPMs), RI-CLPMs can separate 294 between-person variance from within-person variance. We used factor scores as observed 295

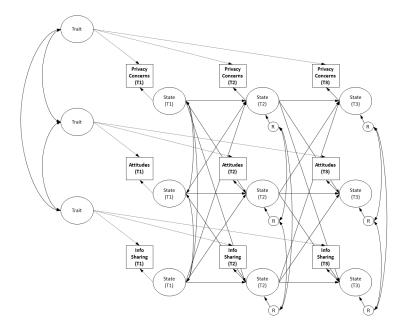

Figure 1. Visual representation of the estimated random-intercept cross-lagged panel model (RI-CLPM).

variables to represent the variables' latent structure more closely. We tested H1, H3.1, and H3.2 by correlating the random intercepts, which represent the respondents' individual 297 mean scores across all three waves. We tested H2, H4.1, and H4.2 by correlating the 298 respondents' within-person variance at T1, which captures their specific deviation at T1 299 from their overall score. We tested all research questions by regressing variables on all other measures obtained 6 months earlier. Given that we had three points of measurement, this resulted in two estimates for each research question. As we did not assume longitudinal effects to differ across time, they were constrained to be equal across all waves, 303 which produces one single general measure of each effect instead of two time-specific ones. 304 (We later tested this assumption empirically. As expected, the model with constrained 305 effects did not show significantly reduced model fit, $\chi^2(9) = .114$, p = 14.25, which 306 supports that effects did not change over time.) Fit was assessed according to the common 307 criteria as described by Kline (2016). The final model fit the data well, $\chi^2(15) = 25.18$, p =308 .048, cfi = 1.00, rmsea = .02, 90% CI [< .01, .04], srmr = .01. 309

For the analyses, coding, and typesetting, we used R (Version 3.6.1; R Core Team, 310 2018) and the R-packages GGally (Version 1.4.0; Schloerke et al., 2018), qqplot2 (Version 311 3.2.1; Wickham, 2016), lavaan (Version 0.6.5; Rosseel, 2012), MissMech (Version 1.0.2; 312 Jamshidian, Jalal, & Jansen, 2014), MVN (Version 5.8; Korkmaz, Goksuluk, & Zararsiz, 313 2014), psych (Version 1.9.12.31; Revelle, 2018), pwr (Version 1.2.2; Champely, 2018), 314 semTools (Version 0.5.2; Jorgensen et al., 2018), and sistats (Version 0.17.9; Lüdecke, 315 2019). The code, additional analyses, and a reproducible version of this manuscript can be 316 found on the manuscript's companion website at 317 https://tdienlin.github.io/privacy-paradox-longitudinal. 318

This study is part of a large-scale project which investigates the development of

privacy and self-disclosure, including severaldother variables. Other publications linked to

319 Procedure and Respondents

320

321

the project can be accessed at https://osf.io/y35as/. The data come from a longitudinal 322 paper-and-pencil questionnaire study, in which a representative sample of the German 323 population (16 years and older) was surveyed on overall five occasions. The data can be 324 downloaded from http://dx.doi.org/10.7802/1937. The first three waves were collected from May 2014 to May 2015, with intervals of 6 326 months each. The last two waves were collected on May 2016 and May 2017, and had an 327 interval of one year. Because we hypothesized the effects to take place across half a year, 328 the last two waves were not included in the analyses presented here. First, a sample of 329 14,714 potential respondents was drawn from a representative omnibus survey in Germany 330 (ADM master sample), employing a random last-two-digit dialing procedure. In this CATI 331 screening, 5,286 respondents agreed to participate in all following waves. Wave 1 was 332 completed by 3,278 respondents (response rate: 38%), Wave 2 by 2,448 respondents 333 (attrition rate: 25%), and Wave 3 by 2,021 respondents (attrition rate: 17%). We filtered 334 respondents who never used the Internet at all waves, answered fewer than 50% of the 335

items in each scale for at least one wave, provided inconsistent birth-dates across measurements, or did not report sociodemographic variables. The final sample consisted of 337 n = 1,403 respondents. 338 In the final sample, the rate of missing data was 5.40%. Visual inspection of the 339 missing value patterns as well as the non-parametric test by Jamshidian et al. (2014) 340 suggested that all missing values could be considered missing at random (p = .514). 341 Therefore, Full Information Maximum Likelihood (FIML) estimation was conducted using 342 all available data. The average age was 54 years (SD = 15 years), and -49% were male. 343 About 39% reported that they had graduated from college.

345 Measures

We tested the factorial validity of all measures using confirmatory factor analysis 346 (CFA). Each CFA included the items from all three waves. For each item, factor loadings 347 were constrained to be equal across waves. Constrained and unconstrained models were 348 compared using χ^2 differences tests. All results were nonsignificant, suggesting longitudinal 349 factorial invariance. The measures showed good composite reliability in all three waves. 350 Graphical displays of the variables' distributions showed that privacy concerns were skewed to the left, privacy attitudes were normally distributed, and information sharing was skewed to the right (Figure 2, diagonal). We calculated intra-class correlation coefficients 353 to quantify how much variance in the variables' factor scores could be attributed to 354 between-person differences. An English translation of the original German items can be 355 found in the OSM. 356

Concerns about online privacy. Privacy concerns were measured as a
second-order factor. Three items captured the vertical dimension (e.g., "How concerned are
you that institutions or intelligence services collect and analyze data that you disclosed on
the Internet?"), and three items captured the horizontal dimension (e.g., "How concerned
are you that people that you do not know might obtain information about you because of

362

387

388

at all concerned) to 5 (very concerned). The means were $M_{\rm t1}=3.67,\,M_{\rm t2}=3.62,\,M_{\rm t3}=$ 363 3.59, and the standard deviations $SD_{\rm t1}=0.88,\,SD_{\rm t2}=0.89,\,{\rm and}\,\,SD_{\rm t3}=0.90.$ The 364 two-dimensional model fit the data well, $\chi^2(118) = 661.17$, p < .001, cfi = .97, rmsea = .06, 365 90% CI [.05, .06], srmr = .04. The reliability was high ($\omega_{t1} = .95, \, \omega_{t2} = .96, \, \omega_{t3} = .97$). 366 Overall, 73.85% of the measure's variance was explained by differences between persons. 367 The online sharing of personal information. To measure respondent's level of 368 information disclosure, they were asked how often they disclosed 10 different pieces of 369 information on the Internet. The exact question was: "How often do you disclose the 370 following pieces of information online (i.e., on the Internet)?" Each item was answered on a 371 5-point scale ranging from 1 (never) to 5 (daily). Factor analyses suggested a second-order 372 factor structure with five first-order factors of two items each. The first first-order factor subsumed financial and medical information, the second first and last name, the third place 374 of residence and street (including house number), the fourth email address and phone 375 number, and the fifth information about education and current job. The means were $M_{\rm t1}$ 376 $= 2.12, M_{\rm t2} = 2.13, M_{\rm t3} = 2.10,$ and the standard deviations $SD_{\rm t1} = 0.66, SD_{\rm t2} = 0.64,$ 377 and $SD_{\rm t3}=0.61.$ The model fit the data adequately, $\chi^2(375)=2527.69,\ p<.001,$ cfi = 378 .95, rmsea = .06, 90% CI [.06, .07], srmr = .06. The reliability was high ($\omega_{\rm t1}$ = .91, $\omega_{\rm t2}$ = 379 .92, $\omega_{\rm t3}$ = .91). Overall, 64.29% of the measure's variance was explained by differences 380 between persons. 381 Attitudes toward the online sharing of personal information. Respondents' 382 attitudes toward disclosing personal information online were captured with 10 items that 383 measured the general appraisal of disclosing the same 10 pieces of information. Adhering to 384 the principle of compatibility (Fishbein & Ajzen, 2010), the items were parallel to those of 385 the actual disclosure scale. Specifically, we asked: "Do you think that it is sensible to 386

disclose the following pieces of information online (i.e., on the Internet)?" The scale ranged

from 1 (not at all sensible) to 5 (very sensible). The means were $M_{\rm t1}=3.67,\,M_{\rm t2}=3.62,$

you online activities?"). Respondents rated all items on a 5-point scale ranging from 1 (not

 $M_{t3} = 3.59$, and the standard deviations $SD_{t1} = 0.88$, $SD_{t2} = 0.89$, and $SD_{t3} = 0.90$. The second-order model with five first-order factors showed an adequate model fit, $\chi^2(375) = 2683.43$, p < .001, cfi = .93, rmsea = .07, 90% CI [.06, .07], srmr = .08. The reliability was high ($\omega_{t1} = .88$, $\omega_{t2} = .89$, $\omega_{t3} = .87$). Overall, 59.19% of the measure's variance was explained by differences between persons.

Results

413

414

In a first descriptive step, we analyzed the variables' bivariate relations. All variables 395 associated with the hypotheses showed correlations that were in line with our theoretical 396 rationales (Figure 2, above the diagonal). 397 Hypothesis 1 predicted that people reporting higher concerns about online privacy 398 than others would also be less likely to share personal information online than others. 399 Results revealed that the random intercepts of the two variables were significantly 400 correlated ($\beta = -.09$, b = -0.03, 95% CI [-0.05, -0.01], z = -2.57, p = .005). Hence, 401 respondents who—on average across all three waves—were more concerned about their 402 privacy than others also shared slightly less personal information online. The effect was 403 small. When looking at the standardized effect's confidence interval (i.e., $\beta = -.09$, 95% CI [-.15, -.02]), it was not significantly smaller than our SESOI of beta = .10. Thus, Hypothesis 1 was supported. 406 Hypothesis 2 proposed that if people perceived more concerns about their online 407 privacy than they usually do, they would also share less personal information online than 408 they usually do. Results revealed a small significant correlation ($\beta = -.10, b = -0.02, 95\%$ 409 CI [-0.03, > -0.01], z = -2.37, p = .009), suggesting that if respondents were more 410 concerned about their online privacy at T1 than usual, they also shared less personal 411 information online at T1 than usual. In conclusion, the results supported Hypothesis 2. 412

With Research Question 1.1, we analyzed the longitudinal relation of concerns about

online privacy and the online sharing of personal information 6 months later. No significant

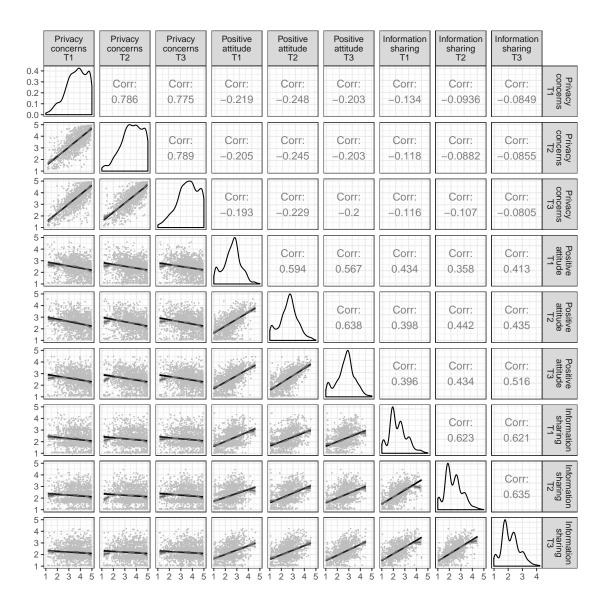

Figure 2. Results of the bivariate relations. Above the diagonal: zero-order correlation matrix; diagonal: density plots for each variable; below the diagonal: bivariate scatter plots for zero-order correlations. Solid regression lines represent linear regressions, dashed regression lines represent quadratic regressions. Calculated with the variables' latent factor scores.

lagged effect across 6 months was found ($\beta = .01$, b = 0.01, 95% CI [-0.05, 0.07], z = 0.41, p = .683). With Research Question 1.2, we investigated the longitudinal relation of the online sharing of personal information and concerns about online privacy 6 months later,

```
again revealing no significant effect (\beta = -.03, b = -0.03, 95% CI [-0.09, 0.04], z = -0.80, p
418
    = .422).
419
         Hypothesis 3.1 predicted that people who perceived more privacy concerns than
420
   others would also hold more negative attitudes toward the online sharing of personal
421
   information than others. The results revealed a medium-sized negative correlation between
422
   the two variables on the between-person level (\beta = -.31, b = -0.11, 95% CI [-0.14, -0.08], z
423
    = -8.46, p < .001). Thus, people who—on average across all three waves—reported being
424
   more concerned about their online privacy relative to the rest of the sample, were also
425
   substantially more likely to hold a more negative attitude toward the online sharing of
426
   personal information. The results therefore supported Hypothesis 3.1. Hypothesis 3.2
427
   stated that people who held more positive attitudes toward the online sharing of personal
428
   information than others would also share more personal information online than others.
   Results showed a very strong between-person correlation between the two variables (\beta =
430
    .66, b = 0.15, 95\% CI [0.13, 0.17], z = 15.12, p < .001). In other words, when averaged
431
   across all three waves, if people had more positive attitudes toward the online sharing of
432
    personal information than others, they were much more likely to actually share personal
433
   information online. In conclusion, the results supported Hypothesis 3.2.
434
         Hypothesis 4.1 proposed that people who perceived more privacy concerns than usual
435
   would also hold more negative attitudes toward the online sharing of personal information
436
   than usual. The results did not reveal a significant effect (\beta = -.06, b = -0.01, 95% CI
437
   [-0.03, < 0.01], z = -1.38, p = .084). Hypothesis 4.2 proposed that people who held more
438
    positive attitudes toward the online sharing of personal information than usual would also
430
   share more personal information online than usual. Results showed a moderate
440
    within-person correlation between the two variables (\beta = .15, b = 0.03, 95% CI [0.02, 0.05],
441
    z = 4.01, p < .001), which indicates that when respondents had more positive attitudes at
442
    T1 than usual, they also shared more personal information than usual. In conclusion, the
443
   results supported Hypothesis 4.2.
```

With Research Question 2.1, we analyzed the longitudinal relations of concerns about 445 online privacy and positive attitudes toward the online sharing of personal information. No 446 significant effect was found ($\beta =$ -.02, b = -0.02, 95% CI [-0.09, 0.06], z = -0.47, p = .641). 447 Regarding Research Question 2.2, again no significant longitudinal relations emerged 448 between privacy attitudes and privacy concerns 6 months later ($\beta < .01$, b < 0.01, 95% CI 449 [-0.06, 0.06], z = 0.06, p = .951. 450 Research Question 3.1 asked whether changes in attitudes toward the online sharing 451 of personal information would affect changes in personal information sharing 6 months 452 later. No significant effect was found ($\beta > -.01, b > -0.01, 95\%$ CI [-0.06, 0.05], z = -0.07, p453 = .947). Next, Research Question 3.2 asked whether changes in the online sharing of 454 personal information would affect attitudes toward the online sharing of personal 455 information 6 months later. Again, no significant effect was found ($\beta = .04$, b = 0.04, 95% CI [-0.03, 0.11], z = 1.15, p = .249).Table 1 presents an overview of all results. 458

459 Discussion

470

Most research on the privacy paradox suggests a significant small effect of privacy concerns on the online sharing of personal information (e.g., Baruh et al., 2017). However, whereas the theoretical premise of the privacy paradox addresses a within-person effect, 462 most empirical studies have analyzed between-person relations. On the basis of a 463 representative sample of the German population, from which three waves of data separated 464 by 6 months were collected, we hence analyzed the privacy paradox by differentiating 465 general between-person relations, short-term within-person relations, as well as long-term 466 within-person effects. Together, this approach allows for informed inferences about the 467 variables' causal relationship. 468 The results of the between-person analyses showed that people who were more 469

concerned about their privacy than others also shared personal information slightly less

Table 1

Parameter Estimates Obtained in the Random-Intercept Cross-Lagged Panel Model

		95% CI			
Effect	b	11	ul	beta	p
Between-person correlations across all waves					
Privacy concern <-> information sharing	-0.03	-0.05	-0.01	09	.005
Privacy concern <-> positive attitude	-0.11	-0.14	-0.08	31	< .001
Positive attitude <-> information sharing	0.15	0.13	0.17	.66	< .001
Within-person correlations at T1					
Privacy concern <-> information sharing	-0.02	-0.03	> -0.01	10	.009
Privacy concern <-> positive attitude	-0.01	-0.03	< 0.01	06	.084
Positive attitude <-> information sharing	0.03	0.02	0.05	.15	< .001
Within-person effects across 6 months					
Privacy concern -> information sharing	0.01	-0.05	0.07	.01	.683
Information sharing -> privacy concern	-0.03	-0.09	0.04	03	.422
Privacy concern -> positive attitude	-0.02	-0.09	0.06	02	.641
Positive attitude -> privacy concern	< 0.01	-0.06	0.06	< .01	.951
Positive attitude -> information sharing	> -0.01	-0.06	0.05	>01	.947
Information sharing -> positive attitude	0.04	-0.03	0.11	.04	.249

Note. The between-person correlations represent interpersonal relations. For example, results showed that people who were more concerned than others, averaged across all three waves, also shared less information than others. The within-person parameters reflect how intrapersonal changes in one variable are related to intra-personal changes in another. For example, results showed that if a person was more concerned at T1 than usual, they also shared less information than usual.

frequently. In addition, people who were more concerned about their privacy than others also held substantially more negative attitudes toward disclosing personal information 472 online. Notably, we found a very strong between-person correlation between attitudes 473 toward information sharing and actual information sharing. This finding shows that typical 474 online disclosure can be predicted precisely by a person's attitude. Taken together, the 475 cross-sectional results are in line with the extant literature: The between-person correlation 476 of privacy concerns and information sharing found in this study (i.e., $\beta = -.08$) fall within 477 the 95% confidence interval of the effect reported by Baruh et al. (2017) (i.e., r = -.13, 478 95% CI [-.07, -.18]). Note that the between-person correlations reported here represent 479 averaged measurements across three waves, which should make the findings more robust 480 than typical one-shot measures. 481 In conclusion, this study suggests that the privacy paradox does not exist on a 482 between-person level. The differences between people with regard to their online 483 information sharing behavior can be explained by differences in privacy concerns to a small extent, and by differences in privacy attitudes to a large extent. The more specific we 485 become, the better we can explain online behavior: Whereas privacy concerns are related 486 only weakly to online information sharing (e.g., Baruh et al., 2017), more specific risks 487 perceptions are related to behavior more closely (e.g., Bol et al., 2018; Yu et al., 2020), 488 whereas behavioral attitudes are the best predictors (Dienlin & Trepte, 2015). 489 The within-person results showed that when a person's privacy concerns increased, 490 the same person also shared slightly less information online than usual. Moreover, people 491 who developed more positive attitudes toward the online sharing of personal information 492 than usual, also shared substantially more personal information online. Together, changes 493 in concerns and attitudes are both related to changes in behavior, which speaks against the 494 privacy paradox also on the within-person level. 495 We did not find any long-term effects, however. Changes in both privacy concerns 496

and attitudes toward the online sharing of personal information were not related to any

meaningful changes in the online sharing of personal information 6 months later, and vice
versa. As an explanation, it might be the case that changes in privacy concern affect
information sharing more immediately. To test this assumption, we would need study
designs with shorter intervals (Keijsers, 2016). Moreover, given that the directions of most
longitudinal relations were in line with the between-person and within-person relations,
longitudinal effects might indeed take place, but only that they are very small. Of course,
it could also be that longterm longitudinal effects do not exist.

505 Limitations

Some of the effect sizes reported in this study are potentially not large enough to refute the privacy paradox completely. On the one hand, they could be a manifestation of the so-called "crud factor" (Meehl, 1990, p. 204), which states that all psychosocial 508 measures are related to one another to some extent. On the other hand, other factors such 500 as expected benefits might play a more important role (Dienlin & Metzger, 2016). In 510 conclusion, although our results suggest that privacy concerns and privacy attitudes are 511 correlated with information sharing, the importance of privacy concerns should not be 512 exaggerated. The effects could be larger, and other variables surely play a role as well. 513 In this study we measured information sharing using self-reports. However, 514 self-reports of frequent and routine behaviors are often imprecise and unreliable (Scharkow, 515 2016). This represents a profound limitation of our study. Whenever possible, future 516 studies should aim to collect objective observations of behavior. 517 Finally, please note that the hypotheses presented in this study were not formally 518 preregistered. At the time when the study was conceived in 2014, we were not yet aware of 519

Future Research

520

521

the importance of preregistration.

Evidence of within-person longitudinal effects is still missing. Although we found significant within-person correlations at T1, they were absent across the 6-month intervals.

- Together, this suggests that longitudinal effects might exist, but that they take place on a different time interval. Future research could hence probe different intervals. For theoretical reasons (e.g., due to availability heuristics), it is plausible to use short intervals; for statistical reasons (e.g., because of the high stability of privacy concerns), however, it also makes sense to test longer intervals (Dormann & Griffin, 2015).
- Although we argue that in most circumstances privacy concerns and behavior should correlate modestly, the exact extent depends on a many boundary conditions. Future research should hence explicitly analyze different contexts and situations. Building on Kokolakis (2017), we suggest the following boundary conditions:
- Context (e.g., professional, social, commercial, or health-related);
 - Situation (e.g., new, habitualized, or unexpected);
- Mood (e.g., positive vs. negative);

534

- Extent of control (high vs. low);
- Type of information processing applied (implicit, heuristic, or peripheral vs. explicit, analytic, or central);
- Existence of bias (e.g., overconfidence, optimism, comparative optimism, or hyperbolic discounting);
- Type of information (e.g., sensitive vs. superficial, biographic, or person-related);
- Benefit immediacy and risk diffusion (high vs. low).
- Specifically, we encourage analyzing privacy behaviors also from a situational perspective, accounting for temporal needs, interpersonal perceptions, contextual cues, or characteristics of communication channels (Masur, 2018). For example, whereas general levels of information sharing are likely best explained by using privacy *concerns*, situational information sharing might be best explained using privacy *heuristics* (Sundar, Kang, Wu, Gu, & Zhang, 2013).
 - Next to these theory-related boundary conditions there are also methodological ones:

- Analysis design (e.g., theoretical, experimental, questionnaire-based, interview-based, or anecdotal);
- Quality of measurement (high vs. low; low quality less likely to detect statistical significance);
- Sample size (small vs. large; small samples less likely to detect statistical significance);
- Statistical analysis (e.g., SEM vs. Regression; analyses without error control less likely to find statistical significance);
- Operationalization (e.g., concerns vs. risk perceptions vs. behavioral attitudes; the more specific, the stronger the relation).

When analyzing the privacy paradox we are likely dealing with small effects (Baruh et al., 2017). Hence, to detect these small effects reliably we need large samples. This is
often not the case (Baruh et al., 2017). In conclusion, we emphasize to use statistical
designs that allow for sufficient statistical power.

63 Conclusion

Being able to show that online behaviors are not paradoxical can be socially relevant. 564 Consider the similar case of fear appeals and protective behavior, where there is also only a 565 small correlation (Witte & Allen, 2000). However, fear appeals are used in public campaigns nonetheless, oftentimes to much success (Wakefield, Loken, & Hornik, 2010). Likewise, proclaiming that the online sharing of personal information is not paradoxical and that concerns about online privacy matter, could lead to more cautious and reflective behavior. It is probably no coincidence that the General Data Protection Regulation, 570 which strengthens the privacy rights of consumers, was passed in Europe, where privacy 571 concerns are particularly pronounced (European Commission, 2015). 572 In sum, this study showed that when people were more concerned about their 573 privacy, they also shared a little less personal information about themselves online. If 574 respondents considered sharing personal information to be insensible, they disclosed 575

- $_{576}$ $\,$ substantially less information. Together, these findings do not support the existence of a
- privacy paradox, at least in this particular context and operationalization. No evidence of
- 578 long-term effects was found, however. Further research is needed to understand the
- potential causal interplay of concerns, attitudes, and behavior.
